- 4 Semantic Parsing

Context

Goal. Categorical formalization of a type-effects system for natural-language semantics (following [BC25]).

Method. Develop a graphical, type-driven parsing formalism that derives sentence meaning compositionally from word meanings.

Typed Semantics for Natural Languages

Expression	Type	λ -Term
planet	$\mathbf{e} \rightarrow \mathbf{t}$	$\lambda x.\text{planet } x$
	Generalizes to common nouns	
carnivorous	$(\mathbf{e} \rightarrow \mathbf{t})$	$\lambda x.\text{carnivorous } x$
	Generalizes to predicative adjectives	
skillful	$(\mathbf{e} \rightarrow \mathbf{t}) \rightarrow (\mathbf{e} \rightarrow \mathbf{t})$	$\lambda p.\lambda x.px \wedge \text{skillful } x$
	Generalizes to predicate modifier adjectives	
Jupiter	\mathbf{e}	$\mathbf{j} \in \text{Var}$
	Generalizes to proper nouns	
sleep	$\mathbf{e} \rightarrow \mathbf{t}$	$\lambda x.\text{sleep } x$
	Generalizes to intransitive verbs	

Syntactic Types and Semantic Types

- What is the type of a **cat** or **Jupiter**, a **planet**?

Syntactic Types and Semantic Types

- What is the type of **a cat** or **Jupiter, a planet**?
- Syntactically, **a cat** and **the cat** should be interchangeable and have the same type.
- No single canonical **cat** exists: that type cannot be **e**.

Syntactic Types and Semantic Types

- What is the type of **a cat** or **Jupiter**, a **planet**?
- Syntactically, **a cat** and **the cat** should be interchangeable and have the same type.
- No single canonical **cat** exists: that type cannot be **e**.

We will use **(side-)effects** to do the difference between them:

$$\mathbf{a\ cat} = \{c \mid \mathbf{cat\ } c\}$$

$$\mathbf{the\ cat} = x \text{ if } \mathbf{cat}^{-1}(\top) = \{x\} \text{ else } \#$$

Effects as Functors

Monads model side-effects [Mog89].

Effects as Functors

Monads model side-effects [Mog89]. Here, **functors suffice**: we may forbid merging/creating effects; lighter structures are useful.

String Diagrams

String Diagrams are a formalism (see [HM23] for example) that allows to visually represent the different threads of a computation and the possible side-effects that appear.

String Diagrams

String Diagrams are a formalism (see [HM23] for example) that allows to visually represent the different threads of a computation and the possible side-effects that appear.

Categorical foundations: [JS91]; Used as a tool for parsing: [CSC10].

Other Categorical Theories

[Mar], and [SM25] use Hopf algebras to give a model for parsing.

They integrate morphological features inside the syntactic structures without breaking the model chosen for syntax.

Notations

- Language: \mathcal{L} ; words compose denotationally.

Notations

- Language: \mathcal{L} ; words compose denotationally.
- Base CCC: \mathcal{C} ; effects: functors $\mathcal{F}(\mathcal{L})$.
- Closure: $\bar{\mathcal{C}}$ = closure of \mathcal{C} under $\mathcal{F}(\mathcal{L})^*$, products and exponentials.

Intuition: all (effect-sequence, base type) combos, with functions/products.

Intuitionistic-style Typing Judgements

We then have typing judgements for basic combinations:

$$\frac{\Gamma \vdash x : \tau \quad \Gamma \vdash F \in \mathcal{F}(\mathcal{L})}{\Gamma \vdash Fx : F\tau} \text{Cons}$$

$$\frac{\Gamma \vdash x : F\tau_1 \quad \Gamma \vdash \varphi : \tau_1 \rightarrow \tau_2}{\Gamma \vdash \varphi x : F\tau_2} \text{fmap}$$

Intuitionistic-style Typing Judgements

We then have typing judgements for basic combinations:

$$\frac{\Gamma \vdash x : \tau_1 \quad \Gamma \vdash \varphi : \tau_1 \rightarrow \tau_2}{\Gamma \vdash \varphi x : \tau_2} \text{App}$$

$$\frac{\Gamma \vdash x : A\tau_1 \quad \Gamma \vdash \varphi : A(\tau_1 \rightarrow \tau_2)}{\Gamma \vdash \varphi x : A\tau_2} \langle * \rangle$$

Intuitionistic-style Typing Judgements

Typing judgements for natural transformations:

$$\frac{\Gamma \vdash x : \tau}{\Gamma \vdash x : A\tau} \text{pure/return}$$

$$\frac{\Gamma \vdash x : MM\tau}{\Gamma \vdash x : M\tau} \gg=$$

$$\forall F \xRightarrow{\theta} G, \quad \frac{\Gamma \vdash x : F\tau \quad \Gamma \vdash G : S' \subseteq \star \quad \tau \in S'}{\Gamma \vdash x : G\tau} \text{nat}$$

Plan

- 2 Category-theoretical type system
 - Type system
 - Introducing a language
- 3 Effect Handling
- 4 Semantic Parsing

Information

To present the language we need:

- The syntax of the language.
- An typed lexicon (possibly with effects).

Updated Lexicon

Expression	Type	λ -Term
it	\mathbf{Ge}	$\lambda g.g_0$
$\cdot, a \cdot$	$\mathbf{e} \rightarrow (\mathbf{e} \rightarrow \mathbf{t}) \rightarrow \mathbf{We}$	$\lambda x.\lambda p.\langle x, px \rangle$
which	$(\mathbf{e} \rightarrow \mathbf{t}) \rightarrow \mathbf{Se}$	$\lambda p.\{x \mid px\}$
the	$(\mathbf{e} \rightarrow \mathbf{t}) \rightarrow \mathbf{Me}$	$\lambda p.x \text{ if } p^{-1}(\top) = \{x\} \text{ else } \#$
a	$(\mathbf{e} \rightarrow \mathbf{t}) \rightarrow \mathbf{De}$	$\lambda p.\lambda s.\{\langle x, x \# s \rangle \mid px\}$
every	$(\mathbf{e} \rightarrow \mathbf{t}) \rightarrow \mathbf{Ce}$	$\lambda p.\lambda c.\forall x, px \Rightarrow cx$

Introducing Higher-Order Constructs

We implement higher-order semantics (e.g. the future and plural)
via functors:

$$\text{future}(\text{be}(\mathbf{I}, \text{a cat})) \xrightarrow{\text{nat}} \text{be}(\text{future}(\mathbf{I}), \text{a cat}) \xrightarrow{\text{nat}} \text{be}(\text{future}(\mathbf{I}), \text{a cat})$$

Introducing Higher-Order Constructs

We implement higher-order semantics (e.g. the future and plural) via functors:

$$\text{future}(\text{be}(\mathbf{I}, \text{a cat})) \xrightarrow{\text{nat}} \text{be}(\text{future}(\mathbf{I}), \text{a cat}) \xrightarrow{\text{nat}} \text{be}(\text{future}(\mathbf{I}), \text{a cat})$$

Those constructs are integrated by using natural transformations explaining their propagation through other effects, as those are purely semantic predicates.

Introducing Higher-Order Constructs

For the plural, this gives:

CN(P)	$\Gamma \vdash p : (\mathbf{e} \rightarrow \mathbf{t})$	$\Pi(p) = \lambda x. (px \wedge x \geq 2)$
ADJ(P)	$\Gamma \vdash p : (\mathbf{e} \rightarrow \mathbf{t})$	$\Pi(p) = \lambda x. (px \wedge x \geq 2)$
	$\Gamma \vdash p : (\mathbf{e} \rightarrow \mathbf{t}) \rightarrow (\mathbf{e} \rightarrow \mathbf{t})$	$\Pi(p) = \lambda \nu. \lambda x. (p(\nu)(x) \wedge x \geq 2)$
NP	$\Gamma \vdash p : \mathbf{e}$	$\Pi(p) = p$
	$\Gamma \vdash p : (\mathbf{e} \rightarrow \mathbf{t}) \rightarrow \mathbf{t}$	$\Pi(p) = \lambda \nu. p(\Pi \nu)$
IV(P)/VP	$\Gamma \vdash p : \mathbf{e} \rightarrow \mathbf{t}$	$\Pi(p) = \lambda o. (po \wedge x \geq 2)$
TV(P)	$\Gamma \vdash p : \mathbf{e} \rightarrow \mathbf{e} \rightarrow \mathbf{t}$	$\Pi(p) = \lambda s. \lambda o. (p(s)(o) \wedge s \geq 2)$

Ambiguity

Handlers

A handler for an effect F is a natural transformation $F \Rightarrow \text{Id}$ ([WSH14]).

Handlers should invert monadic and applicative units: motivating the omission of the unit rule out of certain situations.

Defining Handlers

Two types of handlers:

- 1 Language-Defined Handlers arise from fundamental properties of the considered effects.

Defining Handlers

Two types of handlers:

- 1 Language-Defined Handlers arise from fundamental properties of the considered effects.
- 2 Speaker-dependant handlers which are dependent on the speaker.

Scope Islands

The notion of handlers allows us to enforce the notion of scope islands as introduced in [BC25].

Scope Islands

The notion of handlers allows us to enforce the notion of scope islands as introduced in [BC25].

We would for example have:

$$\mathbf{if} : (\mathbf{t} \setminus \mathcal{F}(\mathcal{L})^* \mathbf{Ct}) \rightarrow \mathbf{t} \rightarrow \mathbf{t}$$

to enforce in the type system the resolution of continuations.

Deformation of String Diagrams

Theorem 3.1 — Theorem 3.1 [Sel10], Theorem 1.2 [JS91] A well-formed equation between morphism terms in the language of monoidal categories follows from the axioms of monoidal categories if and only if it holds, up to planar isotopy, in the graphical language.

Equations on String Diagrams I

Properties of functors, monads, natural transformations, adjunctions and more can be explained in terms of commutative diagrams, but also as string diagrams.

Moreover, Theorem 3.1 can be implemented as string diagram equations.

Confluence of Reductions I

Theorem 3.2 — Confluence Our reduction system is confluent and therefore defines normal forms:

- 1 Right reductions are confluent and therefore define *right* normal forms for diagrams under the equivalence relation induced by exchange.
- 2 Equational reductions are confluent and therefore define *equational* normal forms for diagrams under the equivalence relation induced by exchange.

Confluence of Reductions II

Theorem 3.3 — Normalization Complexity Normalizing a diagram is done in quadratic time in the number of natural transformations in it.

This is accomplished using a formalism based on [DV22].

Reducing the grammar

Combinator denotations to add reductions:

$$>= \lambda\varphi.\lambda x.\varphi x$$

$$\text{ML}_{\mathbf{F}} = \lambda M.\lambda x.\lambda y.(\text{fmap}_{\mathbf{F}} \lambda a.M(a, y))x$$

$$\text{A}_{\mathbf{F}} = \lambda M.\lambda x.\lambda y.(\text{fmap}_{\mathbf{F}} \lambda a.\lambda b.M(a, b))(x) < * > y$$

$$\text{UL}_{\mathbf{F}} = \lambda M.\lambda x.\lambda\varphi.M(x, \lambda b.\varphi(\eta_{\mathbf{F}} b))$$

$$\text{J}_{\mathbf{F}} = \lambda M.\lambda x.\lambda y.\mu_{\mathbf{F}} M(x, y)$$

Reductions

- When two effects commute, we choose an order to apply them.
- We use UR instead of using MR or DNMR when possible.
- We always use modes J, C and DN as early as possible. The fact this works is a consequence of Theorem 3.1 on the denotation diagrams.
- All the rules provided in the previous section can be rewritten here too.

Conclusion

Results:

- Theoretical enhancement of a type system for natural language semantics;

Conclusion

Results:

- Theoretical enhancement of a type system for natural language semantics;
- No more load on the user (comprehension) nor the parser (efficiency).

Conclusion

Results:
